Error Detected: ModuleNotFoundError

"ModuleNotFoundError: No module named pandas"

What does this mean?

Python cannot locate a module you are trying to import. This usually means the package is not installed in the current environment.

Most Likely Root Cause

The package is missing from the active virtual environment or the import name is misspelled.

Step-by-Step Fix

1. Check the exact package name on PyPI -- it may differ from the import name, for example you run `pip install Pillow` but then import `PIL` in your code.
2. Install the missing package by running `pip install <package-name>` in your terminal, making absolutely sure you have activated the correct virtual environment beforehand.
3. Confirm the active Python interpreter is the venv one: run `which python` on macOS/Linux or `where python` on Windows -- the path should point inside your project venv directory.
4. If the module is a local file rather than a published package, add its parent directory to `sys.path` or move the file so it sits in the same directory as the importing script.

Example Fix

```
# Before (raises ModuleNotFoundError)
import pandas

# Fix -- install first, then import
# $ pip install pandas
import pandas as pd
```
